---

The intent of this document is to provide security risk-reduction recommendations. Information provided here does not augment, replace or supersede requirements in the PCI Data Security Standard.
Foreword

The PCI Security Standards Council (PCI SSC) is an open global forum for the ongoing development, enhancement, storage, dissemination, and implementation of security standards for account data protection. The rapid development of payment-acceptance propositions using mobile technologies has led PCI SSC to consider its approach to provide guidance to secure all implementations.

The PCI Security Standards Council charter provides a forum for collaboration across the payment space to develop security standards and guidance for the protection of payment card data wherever it may be stored, processed, or transmitted—regardless of the form factor or channel used for payment. All this applies only when a merchant, service provider, or other entity accepts payment card data from their customers. In other words, when individuals load their own primary account numbers (PAN) into their own devices, the individuals are not required to validate their own devices to PCI standards. Other standards bodies evaluate consumer protection for those scenarios. Conversely, when the same mobile device is transformed into a point of sale (POS) for a merchant to accept account data, there is the responsibility to protect that information. Thus, PCI standards begin to apply when a mobile device is used for payment card acceptance.

This document focuses on payment applications that operate on any consumer electronic handheld device (e.g., smartphone, tablet, or PDA) that is not solely dedicated to payment-acceptance transaction processing and where the electronic handheld device has access to clear-text data. For ease of reference, this subcategory is referred to as “Category 3, Scenario 2.” Separate PCI standards and documentation available on the PCI SSC website deal with all other categories and scenarios:

- Mobile Payment-Acceptance Applications and PA-DSS FAQs
- PCI PTS POI Modular Security Requirements, Version 3.1 (Category 1)
- PCI Payment Application Data Security Standard (PA-DSS), Version 2.0 (Category 2)
- Accepting Mobile Payments with a Smartphone or Tablet (Category 3, Scenario 1)

In June 2011, PCI SSC agreed (see PA-DSS and Mobile Applications FAQs, 22 June 2011) that mobile payment-acceptance applications that qualify as Category 3 will not be considered for PA-DSS validation until the development of appropriate standards to ensure that such applications are capable of supporting a merchant's PCI DSS compliance. The PCI SSC recommends that mobile payment-acceptance applications that fit into Category 3 be developed using PA-DSS requirements and the guidance provided in this document as a baseline.
The purpose of this document is to raise awareness and to provide guidance to those in the best position to protect the trust needed for a payment application that executes within mobile devices: the solution developer. This document encourages development of secure payment-acceptance solutions including applications using secure coding practices, and encourages both monitoring for advancements that improve integrity and preparing for newly discovered threats. While not exhaustive, this document outlines a variety of both traditional and less conventional mechanisms to isolate account data and protect it from exposure.

Disclaimer

Please consider carefully the limitations of this document. In particular:

- No presumption should be made that meeting the guidelines and recommendations expressed in this document would cause a solution to be compliant with PA-DSS. Entities wishing to use such solutions would need to make their own risk assessments around the use of such solutions in consultation with their acquirers and applicable payment brands. Such solutions would be included in an entity’s annual PCI DSS assessment to ensure that the application and its operating environment are compliant with all applicable PCI DSS requirements.

- Due to its rapid evolution, payment brands may have differing approaches to mobile payment acceptance. The guidelines and recommendations expressed in this document may not by themselves be sufficient to meet the specific requirements of all payment brands or territories. For example, manual key entry on a merchant-owned consumer mobile device may be prohibited in some territories but permitted in others. For information and in the event of any doubt, please contact your acquirer and/or the relevant payment brands/territories.
1. Document Overview

1.1 Document Purpose and Scope

The Payment Card Industry Security Standards Council (PCI SSC) recognizes that merchants may use consumer electronic handheld devices (e.g., smartphones, tablets, PDAs, or collectively, “mobile devices”) that are not solely dedicated to payment acceptance for transaction processing. For instance, a merchant might use an off-the-shelf mobile device for both personal use and payment acceptance. Many of these devices have yet to incorporate generally accepted information security standards.

The purpose of this document is to educate stakeholders responsible for the architecture, design, and development of mobile apps and their associated environment within a mobile device that merchants might use for payment acceptance. Developers and manufacturers can use these guidelines to help them design appropriate security controls within their software and hardware products. These controls can then be applied to mobile payment-acceptance environments, thus supporting the deployment of more secure solutions.

This document focuses on two areas: controls that may be currently satisfied by technology in today’s environment, and controls meant to give guidance and direction for the design of mobile payment-acceptance apps and their associated environment within a mobile device. Where merchants’ mobile-device hardware and software implementation cannot currently meet the guidelines documented herein, they may choose to implement a PCI-validated, point-to-point encryption (PCI P2PE) solution. Implementing such a solution would include the addition of a PCI-approved point-of-interaction (POI) device. With the use of a validated solution, account data is encrypted by the POI, and the mobile device simply acts as the conduit through which the encrypted payment transaction is transmitted.

1.2 Security Risks of Mobile Devices

This document defines mobile devices as consumer electronic handheld devices that are not solely dedicated to payment acceptance for transaction processing. These devices span a broad spectrum of features and functions ranging from cellular handsets that only support telephone functionality to “smartphones,” “tablets,” or “PDAs” that have a broader functionality.

Any risk that exists on a standard desktop or laptop computer may also exist on a mobile device. In addition, mobile devices may have a broader set of functionalities than standard desktop and laptop computers, resulting in more security vulnerabilities. Along with the standard communication methods of traditional desktop and laptop computers, mobile devices may also incorporate multiple cellular technologies (e.g., CDMA and GSM), GPS, Bluetooth, infrared (IR), and near-field communication (NFC) capabilities. Risk is further increased by removable media (e.g., SIM card and SD card), the internal electronics used for testing by the manufacturer, embedded sensors (e.g., tilt or motion sensors, thermal sensors, pressure sensors, and light sensors), and biometric readers. Furthermore, vendor and network operator-level logging and debugging configurations may introduce additional risks.
Security risks are also inherent to the developmental life cycle and infrastructure associated with mobile devices. The original equipment manufacturer, the operating-system software developer, the application developer, the integrator, the reseller, the mobile-network operator (or cellular service provider), and the mobile payment-acceptance solution provider each play a part in the overall security of a mobile device. Some developers are involved in multiple stages of the development process, making it potentially easier for them to address more aspects of the device from the silicon layer to the applications running on the operating system; other stakeholders are involved in only one stage of security development. Other third parties may introduce security risks through device drivers, mobile apps, peripheral equipment, and removable media. All of these represent potential vectors for unauthorized access to device operations or unauthorized disclosure of account data. Deciding who is responsible for which best practice may be confusing given the large number of contributors to the development of a mobile device. For more clarity, see the “Best Practices and Responsibilities” matrix in Appendix B.
2. Mobile Payments Guidance Overview

The cardholder data environment (CDE) is comprised of people, processes, and technology that store, process, or transmit cardholder data or sensitive authentication data, including any connected system components. This document does not focus on a PCI-validated P2PE solution, but on providing guidance to reduce security risks in otherwise noncompliant mobile devices. For mobile payment acceptance, the mobile device would be considered part of the CDE with full PCI DSS applicability unless used in tandem with a PCI-validated P2PE solution (refer to the PCI AT-A-GLANCE Mobile Payment Acceptance Security document entitled Accepting Mobile Payments with a Smartphone or Tablet) where the mobile device would act only as a “pass-through” for the encrypted data sent from the POI device.

This document organizes the mobile payment-acceptance security guidelines into the following two sections:

- **Section 3: Objectives and Guidance for the Security of a Payment Transaction**
  This section addresses the three main risks associated with mobile payment transactions: account data entering the device, account data residing in the device, and account data leaving the device.

- **Section 4: Guidelines for the Risk and Controls in the Supporting Environment**
  In addition to the guidelines specific to payment transactions, this section addresses security measures that are essential to the integrity of the mobile platform and associated application environment.
3. Objectives and Guidance for the Security of a Payment Transaction

This section addresses the three main risks associated with mobile payment transactions: account data entering the device, account data residing in the device, and account data leaving the device. An objective with associated guidance is given to address each of the three risks.

Objective 1: Prevent account data from being intercepted when entered into a mobile device.

Guidance:

Ensure account data is appropriately encrypted prior to entry into mobile device. This can be accomplished via a validated PCI P2PE solution.¹

– OR –

Ensure a trusted path² exists between the data-entry mechanism (e.g., manual key entry or entry via a card reader) and the mobile device such that account data cannot be intercepted by an unauthorized party. One option to accomplish this is using a trusted execution environment that restricts access between the mechanism receiving account data and secured memory located inside the device.

If an external device is used for account data entry into the mobile device, that device should also have a means of demonstrating that it is authorized to communicate with the mobile device.

If the external device is wireless (e.g., Wi-Fi or Bluetooth), the wireless communication channel should be secured via strong cryptography.³

Regardless of the process used, assure the account data entry channel is secured against client-side injections. Client-side injections include but are not limited to buffer overflows, data-type mismatches, embedded code or other unexpected data, and malicious or unauthorized apps and services on the mobile device.

Prevent the entry of PIN directly into the mobile device. If the system will permit PIN entry, it should only occur through a PCI PTS-approved PIN entry device or EPP (encrypting PIN pad).

¹ For more information, refer to AT-A-GLANCE Mobile Payment Acceptance Security document entitled Accepting Mobile Payments with a Smartphone or Tablet available at www.pcisecuritystandards.org.
² See Appendix A for the definition of trusted path.
³ See PCI DSS and PA-DSS Glossary of Terms, Abbreviations, and Acronyms for the definition of strong cryptography.
Objective 2: Prevent account data from compromise while processed or stored within the mobile device.

Guidance:

Ensure that account data is only processed inside a trusted execution environment. In order to prevent data leakage, account data should not be accessible outside a trusted execution environment. A data-leakage prevention methodology should be adopted based on industry best practices and guidelines. The methodology should include, but is not limited to:

- Secure distribution of account data
- Secure access to and storage of account data
- Controls over account data while in use (e.g., preventing copy/paste, screen shots, file sharing, and printing)
- Prevention of unintentional or side-channel data leakage

Temporary storage of account data prior to processing and authorization should be in a secured storage environment, such as a secure element, to prevent third-party eavesdropping.

If account data is stored on the mobile device post-authorization, that data should be rendered unreadable per PCI DSS Requirement 3.4. If encrypted account data is stored, any related cryptographic keys need to be managed in accordance with PCI DSS Requirement 3.5 so keys are not accessible to unauthorized people, applications, and/or processes.

Per PCI DSS Requirement 3.2, do not retain sensitive authentication data (SAD) after authorization. This includes ensuring that neither the mobile device nor any attached device retains SAD after authorization.

Objective 3: Prevent account data from interception upon transmission out of the mobile device.

Guidance:

Ensure that account data is encrypted (i.e., using strong symmetric or asymmetric cryptography) per PCI DSS Requirement 4, prior to transmission out of the trusted execution environment of the mobile device.

---

4 OWASP Top 10 Mobile Risks - see Appendix B #10
5 See Appendix A for the definition of sensitive authentication data (SAD)
4. Guidelines for the Risk and Controls in the Supporting Environment

This section addresses security measures essential to the integrity of the mobile platform and associated application environment.

4.1 Prevent unauthorized logical device access.

Protect mobile device from unauthorized logical access. Include design features that prevent unauthorized use. For example, include in the design one of the more secure lock screens: “Face Unlock,” “Password,” “Pattern,” or “PIN.” Do not rely on “Slide,” since it does not add security. Include a feature that would force the user to re-authenticate to the device after a specified amount of time. Bypassing of the lock screen may be prevented by enabling full disk encryption and/or disabling USB debugging.

The mobile app developer should include the capability for the mobile app to determine whether USB debugging is disabled and whether full disk encryption is enabled. In addition, the operating-system developer should include controls that can prevent the user from enabling USB debugging or disabling full disk encryption.

4.2 Create server-side controls and report unauthorized access.

Develop the overall payment-acceptance solution to include capabilities for preventing and reporting unauthorized access attempts, identifying and reporting abnormal activity, and discontinuing access (i.e., the payment-acceptance solution would prevent further access by the mobile payment-acceptance app on that device until an administrator restores access). Controls include, but are not limited to:

- Support for authorized access (e.g., access control list)
- Ability to monitor events and to distinguish normal from abnormal events
- Ability to report events (e.g., via a log, message, or signal) including cryptographic key changes, escalation of privileges, invalid login attempts exceeding a threshold, updates to application software or firmware, and similar actions

4.3 Prevent escalation of privileges.

Controls should exist to prevent the escalation of privileges on the device (e.g., root or group privileges). Bypassing permissions can allow untrusted security decisions to be made, thus increasing the number of possible attack vectors. Controls should include but are not limited to:

- Providing the capability for the device to produce an alarm or warning if there is an attempt to “root” or “jail-break” the device;
Providing the capability within the payment-acceptance solution for identifying authorized objects\textsuperscript{6} and designing controls to limit access to only those objects.

4.4 **Create the ability to remotely disable the payment application.**

The payment application should support a mechanism that permits it to be disabled by the merchant or solution provider responsible for the payment system application. The feature should not interfere with other, non-payment functions of the mobile device.

4.5 **Detect theft or loss.**

A process should exist for the detection and reporting of the theft or loss of the mobile device. Inherent to such a process should be a means for testing and for confirming that it remains active. Examples include the use of GPS or other location technology with the ability to set geographic boundaries, periodic re-authentication of the user, and periodic re-authentication of the device.

4.6 **Harden supporting systems.**

Supporting systems that either provide management for mobile devices or receive payment card data should be hardened to prevent unintended access or exposure of a mobile payment transaction. Therefore, any system used to support the mobile payment-acceptance solution should be compliant with PCI DSS.

4.7 **Prefer online transactions.**

When the mobile payment-acceptance application on the host is not accessible, the mobile device should neither authorize transactions offline nor store transactions for later transmission.

4.8 **Conform to secure coding, engineering, and testing.**

Mobile payment-acceptance applications should conform to secure coding, engineering, and testing conventions, such as the requirements and testing procedures outlined in the *Payment Application Data Security Standard* (PA-DSS). Other examples include CERT Secure Coding Standards\textsuperscript{7}, Institute for Security and Open Methodologies (ISECOM)'s Open Source Security Testing Methodology Manual (OSSTMM)\textsuperscript{8}, or International Systems Security Engineering Association (ISSEA)'s Systems Security Engineering Capability Maturity Model (SSE-CMM – ISO/IEC 21827).\textsuperscript{9}

Developers should be trained on PCI standards. Secure-coding best practices should cover prevention of common coding vulnerabilities in software development processes to include but not be limited to injection flaws, buffer overflow, insecure cryptographic storage, insecure communications, improper error handling, and improper access control.

---

\textsuperscript{6} See Appendix A for the definition of *object*.

\textsuperscript{7} www.cert.org/secure-coding/

\textsuperscript{8} http://www.isecom.org

\textsuperscript{9} http://www.sse-cmm.org/index.html
Developers should also document their implementation and create a formal response plan to identify and mitigate new risk. Developers should establish a process to identify and assign a risk ranking to newly discovered security vulnerabilities and to test their applications for vulnerabilities. Any underlying software or systems that are provided with or required by the application should be included in this process.

4.9 Protect against known vulnerabilities.

Provide a secure means for keeping mobile device software and all applications up-to-date through patch management and other means to prevent compromise of the mobile device due to vulnerable software. Controls should include but are not limited to:

- Evaluate updates prior to implementing them.
- Ensure that updates are received from a trusted source.
- Apply updates in a timely manner.

4.10 Protect the mobile device from unauthorized applications.

All authorized mobile apps, drivers and other software that form part of the payment solution should have a mechanism that permits authentication of the source and integrity of the executable file. The system should prevent the loading and subsequent execution of applications that cannot be authenticated. Developers should ensure that a process exists for the secure distribution of their software such that an end user can determine that the software came from a trusted source before installing it. For instance, it may not be permissible to download apps from an online store whose security cannot be validated.

4.11 Protect the mobile device from malware.

Enhance current capabilities to protect mobile device from malware. Deploy anti-malware products on all systems including antivirus, antispyware, and software-authentication products to protect systems from current and evolving malicious software threats.

Mechanisms (such as a displayed icon) should exist to demonstrate that persistent protection is active and that it is from a trusted source.

4.12 Protect the mobile device from unauthorized attachments.

If an entry device is attached to the mobile device (e.g., card reader)—whether the connection is physical or wireless—it needs to identify itself uniquely to the mobile payment-acceptance app to ensure that the correct entry device is paired to the correct mobile device. Mutual authentication between the entry device and the mobile device provides the best integrity assurance for the path. When the entry device is attached, the mobile payment-acceptance app validates the account data entry device via serial number or other unique identifier.
4.13 Create instructional materials for implementation and use.

Documentation should exist specifically to address the proper, secure use of mobile devices in the merchant environment, including instructional material on the hardware, operating system, and application software.

4.14 Support secure merchant receipts.

Regardless of the method used for producing receipts (e.g., e-mail, SMS, or attached printer), the method should mask the PAN in support of applicable laws, regulations, and payment-card brand policies. Insecure channels such as e-mail and SMS should not be used to send PAN or SAD.

4.15 Provide an indication of secure state.

A trusted execution environment (or equivalent) should include a mechanism for indicating to the mobile-device user that the payment-acceptance mobile app is executing in a secure state. This would be similar to the indication that an SSL session is active in a browser.
Appendix A: Glossary

This glossary contains definitions of words and phrases that are specific to PCI Mobile Payment Acceptance Security Guidelines. For all other definitions please refer to the PCI DSS Glossary.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bluetooth</td>
<td>Wireless protocol using short-range communications technology to facilitate transmission of data over short distances.</td>
</tr>
<tr>
<td>Cardholder data</td>
<td>At a minimum, cardholder data consists of the full PAN. Cardholder data may also appear in the form of the full PAN plus any of the following: cardholder name, expiration date and/or service code. See Sensitive authentication data (SAD) for additional data elements that may be transmitted or processed (but not stored) as part of a payment transaction.</td>
</tr>
<tr>
<td>Card reader</td>
<td>A mechanism for reading data from a payment card.</td>
</tr>
<tr>
<td>Clear-text</td>
<td>Intelligible data that has meaning and can be read or acted upon without the application of decryption.</td>
</tr>
<tr>
<td>Developer</td>
<td>An organization that architects, designs, or builds hardware or software components (e.g., manufacturer, operating-system software company, mobile network operator [MNO], third-party application software company, integrator, or implementer); this may include solution providers or merchants who modify or create hardware or software.</td>
</tr>
<tr>
<td>Encrypting PIN pad (EPP)</td>
<td>A device for secure PIN entry and encryption in an unattended PIN-acceptance device. An EPP may have a built-in display or card reader, or rely upon external displays or card readers installed in the unattended device. An EPP is typically used in an ATM or other unattended device (e.g., an unattended kiosk or automated fuel dispenser) for PIN entry and is controlled by a device controller. An EPP has a clearly defined physical and logical boundary, and a tamper-resistant or tamper-evident shell. Encrypting PIN pads require integration into UPTs or ATMs.</td>
</tr>
<tr>
<td>Entry Device</td>
<td>A type of electronic device that interacts directly with and takes input from humans to facilitate mobile payment acceptance.</td>
</tr>
<tr>
<td>GPS (Global Positioning System)</td>
<td>A satellite communication system that provides location and time information.</td>
</tr>
<tr>
<td>Jail break/jail broken</td>
<td>The rendering of a cell phone such that it is no longer subject to the limitations originally imposed on it by its manufacturers/proprietors. Jail-broken mobile devices allow access to their proprietary operating system, which then allows the installation of third-party applications not released or controlled by the manufacturer or proprietor. Also, see Rooting.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Malicious software/malware</td>
<td>Software designed to infiltrate or damage a computer system without the owner’s knowledge or consent. Examples include viruses, worms, Trojans (or Trojan horses), spyware, adware, and rootkits.</td>
</tr>
<tr>
<td>Mobile app</td>
<td>A program for a phone, tablet, or other mobile electronic device.</td>
</tr>
<tr>
<td>Mobile device</td>
<td>A consumer electronic handheld device (e.g., smartphone, tablet, or PDA) that is not solely dedicated to payment acceptance for transaction processing and that has wireless connectivity to a network (e.g., cellular or Wi-Fi).</td>
</tr>
<tr>
<td>Near field communication (NFC)</td>
<td>A short-range, wireless RFID technology that makes use of interacting electromagnetic radio fields instead of the typical direct radio transmissions. Refer to ISO/IEC 18092 for specifications.</td>
</tr>
<tr>
<td>Object</td>
<td>A process, application, hardware device, or other identity over which access control is exercised.</td>
</tr>
<tr>
<td>PAN</td>
<td>Acronym for “primary account number” and also referred to as “account number.” Unique payment card number (typically for credit or debit cards) that identifies the issuer and the particular cardholder account.</td>
</tr>
<tr>
<td>Rooting</td>
<td>Gaining unauthorized administrative control of a computer system; also, see Jail break/jail-broken.</td>
</tr>
<tr>
<td>Secure Digital (SD) card/Micro-SD card</td>
<td>A non-volatile memory card format often used as additional memory for mobile devices.</td>
</tr>
<tr>
<td>Secure element</td>
<td>A formally certified, tamper-resistant, stand-alone integrated circuit often referred to as a “chip” as defined by the European Payments Council or other recognized standards authority.</td>
</tr>
<tr>
<td>Sensitive authentication data (SAD)</td>
<td>Security-related information (including but not limited to card validation codes/values, full magnetic-stripe data, PINs, and PIN blocks) used to authenticate cardholders and/or authorize payment card transactions.</td>
</tr>
<tr>
<td>Side-channel leakage</td>
<td>An implementation-specific form of information leakage, usually from a cryptographic implementation, in a manner not considered in the data flow model of the implementation. It is generally an exploitation of physical leakages, e.g., power consumption, acoustical vibrations, or electromagnetic radiation. This can facilitate the determination of the secret key and the reconstruction of plaintext data.</td>
</tr>
<tr>
<td>Subscriber identity module (SIM)</td>
<td>A memory card that typically stores the IMSI (International Mobile Subscriber Identity) and other related information used to authenticate subscribers.</td>
</tr>
<tr>
<td>System’s applications</td>
<td>The collection of apps and applications where “apps” refers to the software running on the mobile device and “applications” refers to the software running on the host system (e.g., servers or mainframe computers).</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Trusted execution environment</td>
<td>An execution environment that runs alongside but isolated from an operating system. A trusted execution environment has security capabilities and meets certain security-related requirements: It protects trusted execution environment assets from general software attacks, defines rigid safeguards as to data and functions that a program can access, and resists a set of defined threats. Multiple technologies can be used to implement a trusted execution environment, and the level of security achieved may vary accordingly.</td>
</tr>
<tr>
<td>Trusted path</td>
<td>An unspooofable and incorruptible channel used to move data in and out of a trusted execution environment.</td>
</tr>

Appendix B: Best Practices and Responsibilities

The table below outlines each best practice described within this document along with who should be responsible for its implementation. The definitions of those entities that are responsible for the best practices include:

- **Device Manufacturer (DM):** Includes mobile-device manufacturers, integrators, firmware developers, and any manufacturer responsible for the development of any OEM hardware.
- **OS Developer (OD):** Includes the entity that creates and maintains the operating system, including but not limited to the entity responsible for OS architecture, device drivers, and patch development.
- **Application Developer (AD):** Includes any software developer that creates and maintains an application used as part of the payment-acceptance solution. This includes the merchant as an application developer.
- **Merchant as an End User (M):** Any entity that utilizes the mobile payment-acceptance solution to accept payments.
- **Mobile Payment-Acceptance Solution Provider (SP):** The entity that integrates all pieces in the mobile payment-acceptance solution and is responsible for the back-end administration of the solution. This includes the merchant as a solution provider.

The table below outlines each best practice described within this document along with who should be responsible for its implementation.

Appendix C: Industry Documents and External References

Following are the sources of reference for this document.

The intent of this document is to provide security risk-reduction recommendations. Information provided here does not augment, replace or supersede requirements in the PCI Data Security Standard.
Appendix D: About the PCI Security Standards Council

The mission of the PCI Security Standards Council is to enhance payment account security by driving education and awareness of the PCI Data Security Standard and other standards that increase payment data security.

The PCI Security Standards Council was formed by the major payment card brands American Express, Discover Financial Services, JCB International, MasterCard Worldwide, and Visa Inc. to provide a transparent forum in which all stakeholders can provide input into the ongoing development, enhancement, and dissemination of the PCI Data Security Standard (DSS), PIN Transaction Security (PTS) Requirements, and the Payment Application Data Security Standard (PA-DSS). Merchants, banks, processors, and point-of-sale vendors are encouraged to join as Participating Organizations.
